Abstract

The T0 theory achieves complete parameter freedom: Only the geometric parameter $\xi = \frac{4}{3} \times 10^{-4}$ is fundamental. All physical constants are derived either from ξ or represent unit definitions. For absolute SI values the derivation chain needs one mass or energy anchor; the speed of light is fixed by the definition of the metre and is not determined from ξ . This document provides the complete derivation chain including the gravitational constant G , the Planck length l_P , and the Boltzmann constant k_B . The SI reform 2019 unwittingly implemented the unique calibration consistent with this geometric foundation.

.1 The Geometric Foundation

Single Fundamental Parameter

$$\xi = \frac{4}{3} \times 10^{-4} \quad (1)$$

This geometric ratio encodes the fundamental structure of three-dimensional space. All physical quantities emerge as derivable consequences. (See [1] for the origin of ξ .)

Complete Derivation Framework

Detailed mathematical derivations are available at:

.2 Derivation of the Gravitational Constant from ξ

The Fundamental T0 Gravitational Relationship

Starting point of T0 gravity theory:

The T0 theory postulates a fundamental geometric relationship between the characteristic length parameter ξ and the gravitational constant:

$$\xi = 2\sqrt{G \cdot m_{\text{char}}} \quad (2)$$

where m_{char} represents a characteristic mass of the theory. (Detailed derivation in [2].)

Physical interpretation:

- ξ encodes the geometric structure of space
- G describes the coupling between geometry and matter
- m_{char} sets the characteristic mass scale

Solution for the Gravitational Constant

Solving equation (2) for G :

$$G = \frac{\xi^2}{4m_{\text{char}}} \quad (3)$$

This is the fundamental T0 relationship for the gravitational constant in natural units. (Further details in [3].)

Choice of Characteristic Mass

Insight .2.1. The electron mass follows from the ξ mass ladder:

The T0 theory uses the electron mass as the characteristic scale:

$$m_{\text{char}} = m_e = 0,511 \text{ MeV} \quad (4)$$

Critical point: The electron mass itself is not an independent parameter but follows from the T0 mass ladder (Doc. 006):

$$m_e = \frac{4}{3} \xi^{3/2} \nu \quad (5)$$

The ladder needs ν as a scale; the chain $\xi \rightarrow m_e$ therefore does not work without a mass or energy anchor. (See [4] for mass derivations.)

Therefore, the derivation chain $\xi \rightarrow m_e \rightarrow G \rightarrow l_p$ depends on ξ as the single fundamental parameter and on one anchor for the scale.

Dimensional Analysis in Natural Units

Dimensional check in natural units ($\hbar = c = 1$):

In natural units:

$$[M] = [E] \quad (\text{from } E = mc^2 \text{ with } c = 1) \quad (6)$$

$$[L] = [E^{-1}] \quad (\text{from } \lambda = \hbar/p \text{ with } \hbar = 1) \quad (7)$$

$$[T] = [E^{-1}] \quad (\text{from } \omega = E/\hbar \text{ with } \hbar = 1) \quad (8)$$

The gravitational constant has dimension:

$$[G] = [M^{-1}L^3T^{-2}] = [E^{-1}][E^{-3}][E^2] = [E^{-2}] \quad (9)$$

Checking equation (3):

$$[G] = \frac{[\xi^2]}{[m_e]} = \frac{[1]}{[E]} = [E^{-1}] \neq [E^{-2}] \quad (10)$$

This shows that additional factors are required for dimensional correctness. (See [5] for unit systematics.)

Complete Formula with Conversion Factors

Key Result

Complete gravitational constant formula:

$$G_{\text{SI}} = \frac{\xi_0^2}{4m_e} \times C_{\text{conv}} \times K_{\text{frak}} \quad (11)$$

where:

- $\xi_0 = 1,333 \times 10^{-4}$ (geometric parameter)

- $m_e = 0,511$ MeV (electron mass, anchor of the chain)
- $C_{\text{conv}} = 7,783 \times 10^{-3}$ (SI conversion of the single-anchor chain, Doc. 383)
- $K_{\text{frak}} = 0,986$ (fractal quantum spacetime correction) (See [6].)

Result:

$$G_{\text{SI}} = 6,674 \times 10^{-11} \text{ m}^3/(\text{kg} \cdot \text{s}^2) \quad (12)$$

with +0.003% deviation from the CODATA-2018 value (6.67430×10^{-11}) for $\xi = 4/30000$; with the rounded $\xi_0 = 1.333 \times 10^{-4}$ the deviation is -0.05% .

Here C_{conv} is the SI conversion of the single-anchor chain (Doc. 383); its numerical value 7.783×10^{-3} additionally contains the small residual of this chain (chain value 7.58×10^{-3}). The form of G and its order of magnitude follow from ξ and the one anchor (numerically checked in Doc. 383); with the anchor m_e , G lies at -2.6% , with v at -0.46% . The agreement to 0.003% arises only with this residual and does not count as an independent precision result.

.3 Derivation of the Planck Length from G and ξ

The Planck Length as Fundamental Reference

Definition of the Planck length:

In standard physics, the Planck length is defined as:

$$l_P = \sqrt{\frac{\hbar G}{c^3}} \quad (13)$$

In natural units ($\hbar = c = 1$) this simplifies to:

$$l_P = \sqrt{G} = 1 \quad (\text{natural units}) \quad (14)$$

Physical meaning: The Planck length represents the characteristic scale of quantum gravitational effects and serves as the natural length unit in theories combining quantum mechanics and general relativity. (See [7] for natural and SI units.)

T0 Derivation: Planck Length via G_{SI}

Key Result**Complete derivation chain:**

Since G is derived from ξ via equation (3):

$$G = \frac{\xi^2}{4m_e} \quad (15)$$

the Planck length follows via the complete G_{SI} from Eq. (11), which contains C_{conv} and K_{frak} :

$$l_P = \sqrt{\frac{\hbar G_{\text{SI}}}{c^3}}, \quad G_{\text{SI}} = \frac{\xi^2}{4m_e} C_{\text{conv}} K_{\text{frak}} \quad (16)$$

Result in SI units:

$$l_P = 1,616 \times 10^{-35} \text{ m} \quad (17)$$

The Characteristic T0 Length Scale**Insight .3.1. Connection between r_0 and the fundamental energy scale E_0 :**

The characteristic T0 length r_0 for an energy E is defined as:

$$r_0(E) = 2GE \quad (18)$$

For the fundamental energy scale $E_0 = \sqrt{m_e \cdot m_\mu}$:

$$r_0(E_0) = \frac{\hbar c}{E_0} \approx 2.7 \times 10^{-14} \text{ m} \quad (19)$$

The minimal sub-Planck length scale is:

$$L_0 = \xi \cdot l_P = \frac{4}{3} \times 10^{-4} \times 1,616 \times 10^{-35} \text{ m} = 2,155 \times 10^{-39} \text{ m} \quad (20)$$

Fundamental relationship: In natural units, for any energy E :

$$r_0(E) = \frac{1}{E} \quad (\text{in natural units with } c = \hbar = 1) \quad (21)$$

where the time-energy duality $r_0(E) \leftrightarrow E$ defines the characteristic scale. The fundamental length L_0 marks the absolute lower limit of spacetime granulation and represents the T0 scale, about 10^4 times smaller than the Planck length, where T0-geometric effects become significant. (See [8] for energy scales.)

The Decisive Convergence: Why T0 and SI Agree**Historical****Two paths to the same Planck length:**

There are two ways to determine the Planck length:

Path 1: SI-based (experimental):

$$l_P^{\text{SI}} = \sqrt{\frac{\hbar G_{\text{measured}}}{c^3}} = 1,616 \times 10^{-35} \text{ m} \quad (22)$$

This uses the experimentally measured gravitational constant $G_{\text{measured}} = 6,674 \times 10^{-11} \text{ m}^3/(\text{kg} \cdot \text{s}^2)$ from CODATA.

Path 2: T0-based (geometry and one anchor):

$$m_e = \frac{4}{3} \xi^{3/2} \nu \quad (\text{from } \xi \text{ and the anchor } \nu) \quad (23)$$

$$G = \frac{\xi^2}{4m_e} \times C_{\text{conv}} \times K_{\text{frak}} \quad (\text{from } \xi \text{ and } m_e) \quad (24)$$

$$l_p^{\text{T0}} = \sqrt{\frac{\hbar G}{c^3}} \quad (\text{with } G = G_{\text{SI}} \text{ from Eq. (11)}) \quad (25)$$

Conversion to SI units:

$$l_p^{\text{T0}} = \sqrt{\frac{\hbar}{c^3} \cdot \frac{\xi^2}{4m_e} C_{\text{conv}} K_{\text{frak}}} = \sqrt{\frac{\hbar \cdot 6.6745 \times 10^{-11}}{c^3}} \text{ m} \quad (26)$$

Result: $l_p^{\text{T0}} = 1.616 \times 10^{-35} \text{ m}$

The convergence:

$$l_p^{\text{SI}} = l_p^{\text{T0}} \quad \text{with } +0.002\% \text{ deviation} \quad (27)$$

As for G , this precision arises only with the residual in C_{conv} and does not count as an independent precision result; the deviation is half that of G .

Warning**Why this agreement is not coincidental:**

The agreement between the SI-derived and T0-derived Planck length in form and order of magnitude, which follow from ξ and one anchor, reveals a profound truth:

1. The SI reform 2019 unwittingly calibrated itself to geometric reality
2. Sommerfeld's calibration in 1916 to $\alpha \approx 1/137$ was not arbitrary – it reflected the fundamental geometric value $\alpha = \xi \cdot E_0^2$ (See [9].)
3. The experimental measurement of G does not determine an arbitrary constant – it measures the geometric structure encoded in ξ
4. **The conversion factor:** The factor $\frac{\hbar c}{1 \text{ MeV}} = 1.973 \times 10^{-13} \text{ m}$ converts lengths from natural units ($r_0 = 1/E$) into metres; the agreement of the Planck length itself follows from the complete G_{SI} (Eq. (11)), not from S_{T0} .
5. Both paths describe the same underlying geometric reality: **the universe is pure ξ -geometry**

The SI constants ($c, \hbar, e, k_B$) define *how we measure*, but the *relationships between measurable quantities* are determined by ξ -geometry. Therefore, the SI reform 2019, by fixing these unit-defining constants, unwittingly implemented the unique calibration consistent with T0 theory.

.4 The Role of the Conversion Factor

The Scaling Factor $S_{T0} = 1 \text{ MeV}/c^2$

Key Result

$S_{T0} = 1 \text{ MeV}/c^2$ holds by construction:

The mass scaling factor is

$$S_{T0} = \frac{m_e^{\text{SI}}}{m_e^{\text{T0}}} = 1 \text{ MeV}/c^2 \quad (28)$$

with $m_e^{\text{T0}} = 0.511$. This value arises by construction, because 0.511 is the electron mass in MeV (cf. Doc. 014); it is not a prediction of the MeV scale. The Planck length agrees through G_{SI} and C_{conv} , not through S_{T0} . Where α hides in the conversion and what role the reference energy 1 MeV plays is shown in Doc. 386: the agreement of α requires a reference energy of 0.99992 MeV, whose geometric meaning is open. (See [10] for parameter derivation.)

The Conversion Chain

From natural units to SI units:

The conversion factor between natural T0 units and SI units is:

$$\text{Conversion factor} = \frac{\hbar c}{S_{T0}} = \frac{\hbar c}{1 \text{ MeV}} = 1,973 \times 10^{-13} \text{ m} \quad (29)$$

For the Planck length (with G_{SI} from Eq. (11)):

$$l_P^{\text{SI}} = \sqrt{\frac{\hbar G_{\text{SI}}}{c^3}} \quad (30)$$

$$= \sqrt{\frac{1.0546 \times 10^{-34} \times 6.6745 \times 10^{-11}}{(2.9979 \times 10^8)^3}} \text{ m} \quad (31)$$

$$= 1.616 \times 10^{-35} \text{ m} \quad \checkmark \quad (32)$$

The geometric lock: The agreement of the T0-derived Planck length with the SI-measured value is established through G_{SI} , which contains ξ , m_e (in MeV, i.e. with $S_{T0} = 1 \text{ MeV}/c^2$) and C_{conv} .

The Triple Consistency

Insight .4.1. Three independent measurements lock together:

The system is overdetermined by three independent experimental values:

1. Fine structure constant: $\alpha = 1/137,035999084$ (determined from a_e and atom-recoil measurements $\hbar/m$ on Cs and Rb) (See [11].)
2. Gravitational constant: $G = 6,674 \times 10^{-11} \text{ m}^3/(\text{kg} \cdot \text{s}^2)$ (Cavendish-type experiments)
3. Planck length: $l_P = 1,616 \times 10^{-35} \text{ m}$ (derived from G , $\hbar$, c)

The T0 theory connects all three through ξ and one mass or energy anchor: α via $\alpha = \xi \cdot E_0^2$, G and l_P via G_{SI} with C_{conv} and K_{frak} . The scaling factor $S_{T0} = 1 \text{ MeV}/c^2$ is not an additional boundary condition here but holds by construction. The form and order of magnitude of G

and l_p follow from ξ and the anchor; the agreement to 0.003 % and 0.002 % respectively arises only with the residual in C_{conv} and does not count as an independent precision result.

.5 The Speed of Light: Geometric or Conventional?

The Dual Nature of c

Understanding the role of the speed of light:

The speed of light has a subtle dual character requiring careful analysis:

Perspective 1: As a dimensional convention

In natural units, setting $c = 1$ is purely conventional:

$$[L] = [T] \quad (\text{space and time have the same dimension}) \quad (33)$$

This is analogous to saying 1 hour equals 60 minutes – it's a choice of measurement units, not physics. (See [12].)

Perspective 2: As a ratio of the Planck scales

Via the Planck scales, c can be written as a ratio:

$$l_p = \sqrt{\hbar G / c^3}, \quad G = \frac{\xi^2}{4m_e} C_{\text{conv}} K_{\text{frak}} \quad (34)$$

$$t_p = \frac{l_p}{c} = \frac{l_p}{1} \quad (\text{in natural units}) \quad (35)$$

Since t_p is defined as l_p/c , $c = l_p/t_p$ is an identity and not a determination of c by ξ .

The SI Value is Fixed by Definition

Key Result

Why $c = 299\,792\,458$ m/s exactly:

Since 1983, $c = 299\,792\,458$ m/s has been fixed by the definition of the metre; the value was chosen to match centuries of measurements. The ratio of the Planck scales

$$c^{\text{SI}} = \frac{l_p^{\text{SI}}}{t_p^{\text{SI}}} = \frac{1,616 \times 10^{-35} \text{ m}}{5,391 \times 10^{-44} \text{ s}} \quad (36)$$

reproduces this value because $t_p = l_p/c$ by definition; it is an identity and not a determination of c by ξ .

The Meter is Defined by c

Insight .5.1. The circular calibration loop:

There is a beautiful circularity in the SI-2019 system:

1. The meter is *defined* as the distance light travels in $1/299\,792\,458$ seconds
2. But the number $299\,792\,458$ was chosen to match experimental measurements
3. $c = l_p/t_p$ is an identity because $t_p = l_p/c$; via the Planck scales, c is not determined by ξ

Conclusion: We use c to *define* the meter; the numerical value of c is thus a fixing of the unit of length and does not follow from ξ . (See [13] for circularity of constants.)

.6 Derivation of the Boltzmann Constant

The Temperature Problem in Natural Units

Warning

The Boltzmann constant is NOT fundamental:

In natural units, where energy is the fundamental dimension, temperature is just another energy scale. The Boltzmann constant k_B is purely a conversion factor between historical temperature units (Kelvin) and energy units (Joule or eV). (See [14] for temperature units.)

Definition in the SI System

The SI reform 2019 definition:

Since May 20, 2019, the Boltzmann constant has been fixed by definition:

$$k_B = 1,380649 \times 10^{-23} \text{ J/K} \quad (37)$$

This defines the Kelvin scale in terms of energy:

$$k_B \cdot 1 \text{ K} = 1.380649 \times 10^{-23} \text{ J} \quad (38)$$

Relationship to Fundamental Constants

Key Result

Boltzmann constant from gas constant:

The Boltzmann constant is defined by the Avogadro number:

$$k_B = \frac{R}{N_A} \quad (39)$$

where:

- $R = 8,314462618 \text{ J/(mol}\cdot\text{K)}$ (ideal gas constant)
- $N_A = 6,02214076 \times 10^{23} \text{ mol}^{-1}$ (Avogadro constant, fixed since 2019)

Result:

$$k_B = \frac{8,314462618}{6,02214076 \times 10^{23}} = 1,380649 \times 10^{-23} \text{ J/K} \quad (40)$$

T0 Perspective on Temperature

Insight .6.1. Temperature as an energy scale in T0 theory:

In T0 theory, temperature is naturally expressed as energy:

$$T_{\text{natural}} = k_B T_{\text{Kelvin}} \quad (41)$$

For example, the CMB temperature:

$$T_{\text{CMB}} = 2,725 \text{ K} \quad (42)$$

$$T_{\text{CMB}}^{\text{natural}} = k_B \times 2,725 \text{ K} = 2,35 \times 10^{-4} \text{ eV} \quad (43)$$

Core message: k_B is not derived from ξ because it represents a historical convention for temperature measurement, not a physical property of spacetime geometry.

Distinction ξ_{FFGFT} vs. ξ_{UIFT} : In the IPI discussion, $\xi_{\text{UIFT}} = k_B T_{\text{CMB}} \ln 2 / (m_e c^2) \approx 3.19 \times 10^{-10}$ is treated as an independent parameter. $\xi_{\text{FFGFT}} = 4/30000 \approx 1.333 \times 10^{-4}$ and ξ_{UIFT} are **not the same quantity** — their ratio is:

$$\frac{\xi_{\text{FFGFT}}}{\xi_{\text{UIFT}}} = \frac{\xi m_e c^2}{k_B T_{\text{CMB}} \ln 2} \approx 418\,521 \quad (44)$$

Replacing $k_B T_{\text{CMB}}$ by the FFGFT value $(16/9)\xi \text{ eV}$ gives $\frac{m_e c^2 / \text{eV}}{(16/9) \ln 2} \approx 414\,684$. The factor follows from the SI conversion: $T_{\text{CMB}}[\text{eV}] = k_B \cdot 2.72548 \text{ K} = 2.3486 \times 10^{-4} \text{ eV}$, while FFGFT to first order gives $(16/9)\xi = 2.370 \times 10^{-4} \text{ eV}$ ($\Delta = 0.93\%$).

Static and Dynamic Unit of Information

The factor $\xi_{\text{FFGFT}}/\xi_{\text{UIFT}} \approx 418\,521$ (with the FFGFT value for $k_B T_{\text{CMB}}$: 414 684) is more than a conversion: it separates two fundamentally different notions of “information”. ξ_{UIFT} is defined through $k_B T_{\text{CMB}} \ln 2$ – i.e. through an *energy per bit*, hence through a temperature. ξ_{FFGFT} is dimensionless and reference-free. This is exactly where the question arises of how much energy corresponds to the smallest unit of information.

Insight .6.2. There is no universal energy per bit. The energy of a unit of information is not a fixed quantity but a projection that requires a scale:

$$\begin{aligned} \text{thermal (Landauer): } E &= k_B T \ln 2 \\ &\text{(temperature-dependent)} \end{aligned} \quad (45)$$

$$\begin{aligned} \text{spatial (energy hierarchy): } E_N &= \frac{\hbar c}{L_N} \\ &\text{(length-dependent)} \end{aligned} \quad (46)$$

Both expressions carry the embedding constants (k_B , $\hbar$, c) and an external scale (T or L). The length- or temperature-dependence is therefore not a defect but the *signature of a dynamic projection* (cf. Dok. 184, energy hierarchy $E_N = \hbar c / L_N$, and Landauer bound $k_B T \ln 2$).

In the picture of the static/dynamic demarcation (Dok. 261) this is the *layer-2* answer: an energy per bit exists only once the static structure is embedded in the time-flow and projected onto an absolute scale. This is where ξ_{UIFT} lives – temperature-bound, CMB-referenced, not universal.

The static answer is different. The fundamental unit of information in the static context is not an energy but the *winding number* on the compact torus:

The static unit of information: the winding number. On the compact directions of the torus, winding numbers are topologically conserved and integer-valued (Dok. 181). A winding number is

- **dimensionless and countable** – an integer, not an energy value;
- **reference-free** – independent of L and T , because it lies *before* any projection;
- **universal** – the same counting unit at every scale.

This is exactly the state-space size that, according to Dok. 184, remains untouched by the ξ -dynamics (“the ξ -geometry sets the dynamics, not the state-space size”): the bit as a *state* is static; only its energetic *realization* is dynamic.

The two earlier statements thus resolve without contradiction: *information as energy* is the dynamic projection (layer 2) – scale-dependent, without a universal unit. *Information as counting* (winding, bit) is the static unit (layer 1) – dimensionless and universal. The conversion between them is the *embedding price* (Dok. 185); it explains why a “bit” acquires an energy only through $k_B T$ or $\hbar c/L$ – and why that energy necessarily depends on the scale.

In this light the Vopson comparison appears as a projection ratio: Vopson’s $\xi_{\text{UIFT}} = k_B T_{\text{CMB}} \ln 2 / (m_e c^2)$ is a layer-2 quantity (bound to the CMB temperature through $k_B T_{\text{CMB}}$), while ξ_{FFGF} is the layer-1 invariant. The factor $\approx 418\,521$ is nothing other than the projection factor between a dynamic and a static information quantity.

.7 The Interwoven Network of Constants

The Fundamental Formula Network

SI constants are mathematically linked:

Since the SI reform 2019, all fundamental constants are connected by exact mathematical relationships:

$$\alpha = \frac{e^2}{4\pi\epsilon_0\hbar c} \quad (\text{exact definition}) \quad (47)$$

$$\epsilon_0 = \frac{e^2}{2\alpha\hbar c} \quad (\text{derived from above}) \quad (48)$$

$$\mu_0 = \frac{2\alpha\hbar}{e^2 c} \quad (\text{via } \epsilon_0\mu_0 c^2 = 1) \quad (49)$$

$$k_B = \frac{R}{N_A} \quad (\text{definition of Boltzmann constant}) \quad (50)$$

The Geometric Boundary Condition

Insight .7.1. T0 theory reveals why these specific values are geometrically necessary:

$$\alpha = \xi \cdot E_0^2 = \frac{1}{137,036} \quad (\text{geometric derivation}) \quad (51)$$

This fundamental relationship forces the specific numerical values of the interwoven constants:

$$\frac{e^2}{4\pi\epsilon_0\hbar c} = \frac{1}{137,036} \quad (\text{geometric boundary condition})(\text{See}[17].) \quad (52)$$

.8 The Nature of Physical Constants

Translation Conventions vs. Physical Quantities

Key Result

Constants fall into three categories:

1. **The single fundamental parameter:** $\xi = \frac{4}{3} \times 10^{-4}$
2. **Geometric quantities derivable from ξ (absolute values with one mass or energy anchor):**

- Particle masses (electron, muon, tau, quarks) (See [15].)
- Coupling constants (α , α_s , α_w)
- Gravitational constant G
- Planck length l_P

3. Pure translation conventions (SI unit definitions):

- $\hbar$ (defines energy-time relationship)
- e (defines charge scale)
- k_B (defines temperature-energy conversion)
- c (fixed by the definition of the metre since 1983)

Warning

Critical clarification about the speed of light:

The speed of light occupies a unique position in this classification:

- **In natural units ($c = 1$):** c is a mere convention establishing how we relate length and time
- **In SI units:** The numerical value $c = 299\,792\,458$ m/s has been fixed by the definition of the metre since 1983. The ratio

$$c^{\text{SI}} = \frac{l_P^{\text{SI}}}{t_P^{\text{SI}}} = \frac{1,616 \times 10^{-35} \text{ m}}{5,391 \times 10^{-44} \text{ s}} = 299\,792\,458 \text{ m/s} \quad (53)$$

is an identity because $t_P = l_P/c$, not a determination of c by ξ .

The consequence: In natural units $c = 1$ is a convention, in SI units a fixing of the metre; in neither case does ξ determine the numerical value of c .

The SI Reform 2019: Geometric Calibration Realized

The 2019 redefinition fixed constants by definition:

$$c = 299\,792\,458 \text{ m/s} \quad (54)$$

$$\hbar = 1,054571817... \times 10^{-34} \text{ J} \cdot \text{s} \quad (55)$$

$$e = 1,602176634 \times 10^{-19} \text{ C} \quad (56)$$

$$k_B = 1,380649 \times 10^{-23} \text{ J/K} \quad (57)$$

Insight .8.1. This fixation implements the unique calibration consistent with ξ -geometry. The apparent arbitrariness conceals geometric necessity.

.9 The Mathematical Necessity

Why Constants Must Have Their Specific Values

The interlocked system:

Given the fixed values and their mathematical relationships:

$$h = 2\pi\hbar = 6,62607015 \times 10^{-34} \text{ J} \cdot \text{s} \quad (58)$$

$$\alpha = \frac{e^2}{4\pi\epsilon_0\hbar c} = \frac{1}{137,035999084} \quad (59)$$

$$\epsilon_0 = \frac{e^2}{2\alpha\hbar c} = 8,8541878128 \times 10^{-12} \text{ F/m} \quad (60)$$

$$\mu_0 = \frac{2\alpha\hbar}{e^2 c} = 1,25663706212 \times 10^{-6} \text{ N/A}^2 \quad (61)$$

These are not independent choices but mathematically enforced relationships. (See [16] for mathematical structure.)

The Geometric Explanation

Historical

Sommerfeld's unwitting geometric calibration

Arnold Sommerfeld's calibration in 1916 to $\alpha \approx 1/137$ established the SI system on geometric foundations. T0 theory reveals this was not coincidental but reflected the fundamental value $\alpha = 1/137,036$ derived from ξ . (See [18].)

.10 Conclusion: Geometric Unity

Key Result

Complete parameter freedom achieved:

- **Single input:** $\xi = \frac{4}{3} \times 10^{-4}$
- **Derivable from ξ (absolute SI values with one mass or energy anchor):**
 - **First:** Particle masses including the electron via the ladder $m_e = \frac{4}{3} \xi^{3/2} \nu$ (Doc. 006), with ν as the scale
 - **Then:** Gravitational constant: $G = \xi^2 / (4m_e) \times$ (conversion factors)
 - **Then:** Planck length: $l_p = \sqrt{\hbar G / c^3}$ with the complete G
 - **Also:** Characteristic T0 length: $L_0 = \xi \cdot l_p$ (spacetime granulation)
 - Coupling constants: $\alpha, \alpha_s, \alpha_w$
- **Translation conventions (not derived, define units):**
 - $\hbar$ defines energy-time relation in SI units
 - e defines charge scale in SI units
 - k_B defines temperature-energy conversion (historical)
 - c defines the metre (fixed by definition since 1983)
- **Mathematical necessity:** Constants intertwined through exact formulas
- **Geometric foundation:** SI 2019 unwittingly implements ξ -geometry

Final insight: The universe is pure geometry, encoded in ξ . The complete derivation chain is:

$$\xi \rightarrow \{m_e, m_\mu, m_\tau, \dots\} \rightarrow G \rightarrow l_P$$

with $L_0 = \xi \cdot l_P$, expressing the fundamental sub-Planck scale of spacetime granulation.

The profound mystery resolved: Why does the Planck length, derived from ξ -geometry and one anchor, agree with the Planck length calculated from experimentally measured G ? Because *both describe the same geometric reality*: form and order of magnitude follow from ξ and the anchor; the precision to 0.002 % arises only with the residual in C_{conv} . The SI reform 2019 unwittingly calibrated human measurement units to the fundamental ξ -geometry of the universe.

This is no coincidence – it is geometric necessity. Only ξ is fundamental; everything else either follows from geometry or defines how we measure this geometry.

Appendix: Complete Derivation Chain

From geometric parameter to measurable quantities:

1. Basic parameter: $\xi = \frac{4}{3} \times 10^{-4}$
2. Electron mass: $m_e = \frac{4}{3} \xi^{3/2} \nu$ (Doc. 006), with ν as mass or energy anchor
3. Gravitational constant: $G = \frac{\xi^2}{4m_e} \times C_{\text{conv}} \times K_{\text{frak}}$
4. Planck length: $l_P = \sqrt{\hbar G / c^3}$ with G from step 3
5. Planck time: $t_P = l_P / c = l_P$ (natural units)
6. Speed of light: $c = l_P / t_P$ is an identity because of step 5; $c = 299\,792\,458$ m/s is fixed by the definition of the metre
7. Fundamental length: $L_0 = \xi \cdot l_P = 2,155 \times 10^{-39}$ m
8. Fine structure constant: $\alpha = \xi \cdot E_0^2 = 1/137,036$

Consistency check:

$$\Delta G = \left| \frac{G_{\text{T0}} - G_{\text{SI}}}{G_{\text{SI}}} \right| \approx 0.003\% \quad (62)$$

$$\Delta l_P = \left| \frac{l_P^{\text{T0}} - l_P^{\text{SI}}}{l_P^{\text{SI}}} \right| \approx 0.002\% \quad (63)$$

$$\Delta \alpha = \left| \frac{\alpha_{\text{T0}} - \alpha_{\text{SI}}}{\alpha_{\text{SI}}} \right| \approx 0.0005\% \quad (64)$$

The agreement of G and l_P at this level arises only with the residual in C_{conv} and does not count as an independent precision result.

Glossary

ξ Fundamental geometric parameter, $\frac{4}{3} \times 10^{-4}$

S_{T0} Mass scaling factor, 1 MeV/ c^2 (by construction)

L_0 Fundamental T0 length, $\xi \cdot l_P = 2,155 \times 10^{-39}$ m

E_0 Fundamental energy scale, $\sqrt{m_e \cdot m_\mu / K_{\text{frak}}} = 7.398$ MeV (bare $\sqrt{m_e m_\mu} = 7.348$ MeV)

$r_0(E)$ Characteristic length for energy E , $2GE$
