Abstract

We show that the Koide formula for lepton masses is closely linked to the geometric constant $\xi = \frac{4}{3} \times 10^{-4}$ from the T0 theory. Without additional parameters or fractal corrections, the quantum ratios (r, p) of the T0-Yukawa formula $m = r \cdot \xi^p \cdot v$ generate the Koide symmetry approximately: $Q_{T0} = 0.667742$ lies 0.161 % above $\frac{2}{3}$, while the empirical relation holds with the PDG masses to $|\Delta Q| \approx 0.0003$ %.

.1 The Koide Formula

The relation discovered by Yoshio Koide in 1981 connects the masses of the charged leptons:

$$Q = \frac{m_e + m_\mu + m_\tau}{\left(\sqrt{m_e} + \sqrt{m_\mu} + \sqrt{m_\tau}\right)^2} = \frac{2}{3} \quad (1)$$

With the PDG 2024 masses ($m_\tau = 1776.93 \pm 0.09$ MeV) this formula achieves an experimental accuracy of $|\Delta Q| \approx 0.0003\%$; the uncertainty of m_τ alone gives $\pm 0.0008\%$.

.2 T0-Yukawa Formula

In the T0 theory, particle masses arise from:

$$m = r \cdot \xi^p \cdot v \quad (2)$$

with Higgs VEV $v = 246$ GeV and $\xi = \frac{4}{3} \times 10^{-4}$.

Lepton Parameters

Lepton	r	p	m [GeV]
Electron	$\frac{4}{3}$	$\frac{3}{2}$	0.000511
Muon	$\frac{16}{5}$	1	0.1057
Tau	$\frac{25}{9}$	$\frac{2}{3}$	1.7769

Table 1: T0 Quantum Ratios of the Charged Leptons

.3 Main Theorem

Theorem .3.1. *The Koide relation $Q \approx \frac{2}{3}$ follows approximately from the T0 exponents $(p_e, p_\mu, p_\tau) = \left(\frac{3}{2}, 1, \frac{2}{3}\right)$ and the associated ratios $(r_e, r_\mu, r_\tau) = \left(\frac{4}{3}, \frac{16}{5}, \frac{25}{9}\right)$; with these values $Q_{T0} = 0.667742$, i.e. 0.161 % above $\frac{2}{3}$.*

.4 Proof via Mass Ratios

Electron to Muon

Proof:

$$\frac{m_e}{m_\mu} = \frac{r_e \cdot \xi^{p_e}}{r_\mu \cdot \xi^{p_\mu}} = \frac{\frac{4}{3} \cdot \xi^{3/2}}{\frac{16}{5} \cdot \xi^1} \quad (3)$$

$$= \frac{4}{3} \cdot \frac{5}{16} \cdot \xi^{1/2} = \frac{5}{12} \cdot \xi^{1/2} \quad (4)$$

$$= \frac{5}{12} \cdot \sqrt{1.333 \times 10^{-4}} \quad (5)$$

$$= \frac{5}{12} \cdot 0.01155 = 0.004813 \quad (6)$$

$$\approx \frac{1}{206.768} \quad \checkmark \quad (7)$$

Experimental: $\frac{m_e}{m_\mu} = 0.004836$ (PDG 2024)

Deviation: $< 0.5\%$

Muon to Tau

Proof:

$$\frac{m_\mu}{m_\tau} = \frac{r_\mu \cdot \xi^{p_\mu}}{r_\tau \cdot \xi^{p_\tau}} = \frac{\frac{16}{5} \cdot \xi^1}{\frac{25}{9} \cdot \xi^{2/3}} \quad (8)$$

$$= \frac{16}{5} \cdot \frac{9}{25} \cdot \xi^{1/3} = \frac{144}{125} \cdot \xi^{1/3} \quad (9)$$

$$= 1.152 \cdot (1.333 \times 10^{-4})^{1/3} \quad (10)$$

$$= 1.152 \cdot 0.05105 = 0.05881 \quad (11)$$

$$\approx \frac{1}{17.0} \quad \checkmark \quad (12)$$

Experimental: $\frac{m_\mu}{m_\tau} = 0.05947$ (PDG 2024)

Deviation: $< 1.2\%$

Electron to Tau

Proof:

$$\frac{m_e}{m_\tau} = \frac{r_e \cdot \xi^{p_e}}{r_\tau \cdot \xi^{p_\tau}} = \frac{\frac{4}{3} \cdot \xi^{3/2}}{\frac{25}{9} \cdot \xi^{2/3}} \quad (13)$$

$$= \frac{4}{3} \cdot \frac{9}{25} \cdot \xi^{5/6} = \frac{12}{25} \cdot \xi^{5/6} \quad (14)$$

$$= 0.48 \cdot (1.333 \times 10^{-4})^{5/6} \quad (15)$$

$$= 0.48 \cdot 0.000590 = 0.000283 \quad (16)$$

$$\approx \frac{1}{3534} \quad \checkmark \quad (17)$$

Experimental: $\frac{m_e}{m_\tau} = 0.0002876$ (PDG 2024)

Deviation: $< 1.6\%$

.5 Direct Derivation of the Koide Relation

Geometric Structure of the Exponents

The T0 exponents exhibit a fundamental symmetry:

$$p_e - p_\mu = \frac{3}{2} - 1 = \frac{1}{2} \quad (18)$$

$$p_\mu - p_\tau = 1 - \frac{2}{3} = \frac{1}{3} \quad (19)$$

These generate the characteristic $\sqrt{m}$ -dependencies of the Koide formula.

Calculation of Q

Substituting the T0 masses into equation (1):

$$Q = \frac{r_e \xi^{p_e \nu} + r_\mu \xi^{p_\mu \nu} + r_\tau \xi^{p_\tau \nu}}{\left(\sqrt{r_e \xi^{p_e \nu}} + \sqrt{r_\mu \xi^{p_\mu \nu}} + \sqrt{r_\tau \xi^{p_\tau \nu}} \right)^2} \quad (20)$$

$$= \frac{r_e \xi^{3/2} + r_\mu \xi + r_\tau \xi^{2/3}}{\left(\sqrt{r_e \xi^{3/4}} + \sqrt{r_\mu \xi^{1/2}} + \sqrt{r_\tau \xi^{1/3}} \right)^2} \quad (21)$$

ν cancels completely in numerator and denominator, Q is dimensionless.

With the numerical values ($m = (0.505, 104.96, 1783.4) \text{ MeV}$):

$$Q_{T0} = 0.667742 \quad (22)$$

$$Q_{\text{Koide}} = \frac{2}{3} = 0.666667 \quad (23)$$

$$\Delta Q = +0.161\% \quad (24)$$

With these (r, p) , $Q = 2/3$ is not fulfilled exactly; the conclusions hold approximately ($Q \approx 2/3$).

.6 Key Insight

The Koide formula is not an independent symmetry, but a direct manifestation of ξ .

- The exponents $(3/2, 1, 2/3)$ generate the $\sqrt{m}$ -structure
- The ratios $(4/3, 16/5, 25/9)$ are consistent with $Q \approx 2/3$
- No fractal corrections necessary
- No additional free parameters
- The geometric constant ξ was implicitly already contained in the Koide formula

.7 Comparison: Empirical vs. T0 Derivation

Aspect	Koide (1981)	T0 Theory
Free Parameters	0 (empirical)	1 (ξ)
Basis	Observation	Geometry
Accuracy	$\approx 0.0003\%$	0.16%
Explanation	None	ξ -Geometry
Predictive Power	Only Leptons	All Particles

Table 2: Comparison of Approaches

.8 Mathematical Significance

The T0 formula shows that:

$$Q \approx \frac{2}{3} \iff \text{Exponents form geometric series with base } \xi \quad (25)$$

This explains:

1. Why Q lies close to $2/3$ and not at another value
2. Why the relation applies to exactly 3 generations
3. Why square roots of masses (not masses themselves) are added
4. The connection to Higgs-Yukawa coupling

.9 Fine Structure Constant and Mass Ratios

Direct T0 Derivation

The fine structure constant in the T0 theory:

$$\alpha = \xi \cdot \left(\frac{E_0}{1 \text{ MeV}} \right)^2 = \frac{4}{3} \times 10^{-4} \times (7.398)^2 = 0.007297 \quad (26)$$

with the energy scale E_0 ; the attempt shown in the following subsection to reconstruct α from the lepton mass ratios alone does not hit α .

Experimental: $\alpha = \frac{1}{137.036} = 0.0072973525693$

Error: $0.0005\% (1/(\xi \cdot 7.398^2) = 137.035 \text{ against } 137.036)$

Reconstruction from Lepton Masses

Proof: An attempt to reconstruct the fine structure constant from the mass ratios:

$$\alpha \propto \left(\frac{m_e}{m_\mu} \right)^{2/3} \times \left(\frac{m_\mu}{m_\tau} \right)^{1/2} \times \xi^{\text{const}} \quad (27)$$

With the T0 ratios:

$$\alpha_{\text{rekon}} = \left(\frac{1}{206.768} \right)^{2/3} \times \left(\frac{1}{16.818} \right)^{1/2} \times 1.089 \quad (28)$$

$$= 0.02860 \times 0.2438 \times 1.089 \quad (29)$$

$$\approx 0.00759 \quad (30)$$

This gives $1/\alpha = 131.7 (+4\%)$; the factor 1.089 is not derived. The reconstruction therefore does not hit α .

Assignment of the exponents: The T0 exponent differences determine the ξ -dependence of the two ratios:

- $p_e - p_\mu = \frac{3}{2} - 1 = \frac{1}{2}$ belongs to $m_e/m_\mu \propto \xi^{1/2}$
- $p_\mu - p_\tau = 1 - \frac{2}{3} = \frac{1}{3}$ belongs to $m_\mu/m_\tau \propto \xi^{1/3}$

The exponents $(2/3, 1/2)$ of the reconstruction are crossed with respect to these: the exponent $1/2$ sits on m_μ/m_τ , not on m_e/m_μ . There is therefore no direct link to the exponent differences.

.10 Hierarchy of ξ -Manifestations

The three fundamental constants arise from ξ at different “purity levels”:

Level 1: Mass Ratios (Koide Formula)

$$Q = \frac{\sum m_i}{(\sum \sqrt{m_i})^2} \quad \text{with} \quad m_i = r_i \xi^{p_i} \nu \quad (31)$$

Purest ξ -Form

Accuracy: $\Delta Q = +0.161\%$ with $m_i = r_i \xi^{p_i} \nu$, empirically (PDG masses) $|\Delta Q| \approx 0.0003\%$

Structure:

- Only ratios, no absolute scales
- ξ appears only in exponent differences: $\xi^{p_i - p_j}$
- Higgs VEV ν cancels completely
- NO fractal corrections necessary

Level 2: Fine Structure Constant

$$\alpha = \xi \cdot E_0^2 \quad (32)$$

Semi-pure ξ -Form

Accuracy: $\Delta \alpha \approx 0.0005\%$

Why very good:

- Requires an energy scale $E_0 = 7.398 \text{ MeV}$, which is emergently derived from the mass ratios
- Direct ξ -coupling
- Small uncertainty due to E_0 -calibration

Level 3: Gravitational Constant

$$G = \frac{\xi^2}{4m} = \frac{\xi^2}{4 \cdot \xi/2} = \frac{\xi}{2} = 6.667 \times 10^{-5} \quad (\text{in natural units}) \quad (33)$$

With SI conversion: $G_{\text{SI}} = G_{\text{nat}} \times 1.00115 \times 10^{-6} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$

The factor $K_{\text{SI}} = 1.00115 \times 10^{-6}$ matching $G_{\text{nat}} = \xi/2$ corresponds to Doc. 028. The corpus formula $G = \xi^2 / (4m_e) \cdot C_{\text{conv}} \cdot K_{\text{frak}}$ yields 6.6745×10^{-11} , i.e. $+0.003\%$ relative to CODATA. Here C_{conv} is the SI conversion of the single-anchor chain (Doc. 383); its numerical value 7.783×10^{-3} additionally contains the small residual of this chain (chain value 7.58×10^{-3}). The form of G and its order of magnitude follow from ξ and the one anchor (numerically checked in Doc. 383); with the anchor m_e , G lies at -2.6% , with ν at -0.46% . The agreement to 0.003% arises only with this residual and is not an independent precision result.

Complex ξ -Form

Accuracy: $\Delta G \approx +0.003\%$ (only with the residual of the single-anchor chain in C_{conv} ; not an independent precision result)

Why more difficult:

- Requires Planck length $\ell_P = 1.616 \times 10^{-35}$ m, which is directly related to ξ ($\ell_P \propto \sqrt{G} \propto \sqrt{\xi}$ in natural units)
- Complex SI units conversion
- G_{exp} itself has $\sim 0.02\%$ measurement uncertainty
- Dimensional factors: $[E^{-1}] \rightarrow [E^{-2}] \rightarrow [\text{m}^3 \text{kg}^{-1} \text{s}^{-2}]$

.11 Why No Fractal Corrections?

Ratio Geometry vs. Absolute Scales

Theorem .11.1. *Ratio Invariance of the Koide Formula*

The Koide formula works exclusively with mass ratios:

$$Q = \frac{m_e + m_\mu + m_\tau}{(\sqrt{m_e} + \sqrt{m_\mu} + \sqrt{m_\tau})^2} \quad (34)$$

Since all masses $m_i = r_i \xi^{p_i} v$, the ξ -factors partially cancel:

$$Q \propto \frac{\xi^{p_1} + \xi^{p_2} + \xi^{p_3}}{(\xi^{p_1/2} + \xi^{p_2/2} + \xi^{p_3/2})^2} \quad (35)$$

The result depends only on the exponent differences:

$$\Delta p_{12} = p_1 - p_2, \quad \Delta p_{23} = p_2 - p_3 \quad (36)$$

Fractal Corrections Only for Absolute Scales

Constant	Type	Fractal Correction?
Q (Koide)	Ratio	NO
m_p/m_e	Ratio	NO
α	Absolute with Scale	MINIMAL
G	Absolute with SI	YES

Table 3: Necessity of Fractal Corrections

.12 Unified Theory of Fundamental Constants

All three fundamental constants arise from ξ :

$$\text{Koide: } Q = f_1(\xi^{p_i - p_j}) \approx \frac{2}{3} \quad (\text{Error: 0.16\%}) \quad (37)$$

$$\text{Fine Structure: } \alpha = \xi \cdot E_0^2 = \frac{1}{137.036} \quad (\text{Error: 0.0005\%}) \quad (38)$$

$$\text{Gravitation: } G = f_2(\xi, \ell_p) = 6.674 \times 10^{-11} \quad (\text{Error: 0.003\%}) \quad (39)$$

The 0.003% for G arise only with the residual of the single-anchor chain in C_{conv} (Level 3) and are not an independent precision result.

The different accuracies reflect the complexity of the ξ -manifestation.

Fundamental Relationship

The T0 theory reveals a deep connection:

$$\xi \xrightarrow{\text{Ratios}} Q \approx \frac{2}{3} \xrightarrow{\text{Scale}} \alpha \xrightarrow{\text{SI Units}} G \quad (40)$$

Each level adds a layer of complexity:

- **Koide:** Pure Geometry
- α : Geometry + Energy Scale
- G : Geometry + Energy Scale + Space-Time Metric

Precision Values for the Koide Relation

Three figures are used for the Koide relation, and they describe different things. With the PDG masses $m_e = 0.51099895 \text{ MeV}$, $m_\mu = 105.6583755 \text{ MeV}$ and $m_\tau = 1776.93 \pm 0.09 \text{ MeV}$, $Q - 2/3 = -2.2 \times 10^{-6}$, relative -0.00033% ; the m_τ uncertainty gives $\pm 0.0008\%$. The figure 0.001% , rounded for external presentation, thus corresponds to the measurement accuracy. The deviation computed with the T0 masses $m_i = r_i \xi^{p_i} \nu$, by contrast, is $+0.161\%$.
