Correction notes

Corrections from the calculation review (1 Oct. 2026). The following passages are corrected or annotated in the text; each carries a dated note with the previous value:

- Doc. 064: note on the dimension of $dE/dx = -\xi E$ and $z \approx \xi x$ (an inverse length such as H_0/c is missing); note below the dimensional-analysis table (rows energy loss rate and redshift).

Abstract

The T0 model interprets cosmological redshift not as expansion but as energy loss of photons in the universal ξ -field. This document treats the field-theoretic energy loss mechanism and its connection to the Hubble constant. The quantitative derivation of $H_0 \approx 66.2$ km/s/Mpc, unit conversion, frequency independence, and the resolution of the Hubble tension are centralized in Document 026 (Geometric Cosmology).

.1 Introduction: Rethinking the Hubble Constant

The conventional interpretation of Hubble's law assumes galaxies recede due to expanding space ($v = H_0 d$). This expansion paradigm requires 69% dark energy, suffers from persistent measurement tensions, and fine-tuning problems.

The T0 model offers a fundamentally different perspective: the universe is static, and the observed redshift arises from energy loss of photons as they propagate through the universal ξ -field. The Hubble constant thus transforms from a measure of space expansion into a characteristic energy loss rate.

The time-energy duality ($\Delta E \cdot \Delta t \geq \hbar/2$) forbids a temporal beginning of the universe: a finite time interval from a singularity would require infinite energy uncertainty. The universe must have existed eternally, making space expansion unnecessary for explaining cosmic observations.

.2 The Universal ξ -Field

The cornerstone of the T0 model is the universal geometric constant:

$$\xi = \frac{4}{3} \times 10^{-4} = 1.3333 \dots \times 10^{-4} \quad (1)$$

This dimensionless constant determines a characteristic energy scale:

$$E_\xi = \frac{1}{\xi} = 7500 \quad (\text{natural units}) \quad (2)$$

The ξ -field permeates all of space and mediates interactions between photons and the vacuum. Its dynamics are described by the wave equation:

$$\square E_{\text{field}} = \left(\nabla^2 - \frac{\partial^2}{\partial t^2} \right) E_{\text{field}} = 0 \quad (3)$$

.3 Energy Loss Mechanism

Fundamental Energy Loss Equation

Photons lose energy through interaction with the ξ -field. The rate of energy loss follows the differential equation:

$$\frac{dE}{dx} = -\xi \cdot E \quad (4)$$

The negative sign indicates energy loss; the linear dependence on E ensures that the resulting redshift is frequency-independent (see Document 026 for the geometric justification).

Solution for Cosmological Distances

For cosmological observations ($\xi x \ll 1$), the perturbative solution yields:

$$E(x) = E_0 (1 - \xi \cdot x) \quad (5)$$

The redshift is therefore:

$$z = \frac{E_0 - E(x)}{E(x)} \approx \xi \cdot x \quad (6)$$

(Note of 1 Oct. 2026: With dimensionless ξ , $-\xi E$ has dimension $[E]$, whereas dE/dx in natural units has $[E^2]$; likewise $\xi \cdot x$ has the dimension of a length $[E^{-1}]$ and is not dimensionless. The equations lack an inverse length, e.g. $dE/dx = -(H_0/c) E$ and $z \approx H_0 x/c$. With x in metres, $z = \xi x$ would already reach $z = 1$ at $x = 1/\xi = 7500 \text{ m}$.)

This relationship reproduces the observed linear Hubble law without space expansion.

.4 Connection to the Hubble Constant

Comparison with Hubble's law $z = H_0 d/c$ yields in natural units ($c = 1$):

$$H_0^{\text{T0}} = E_H/\hbar, \quad E_H = E_0 \cdot \xi^{41/4} = 1.41 \times 10^{-33} \text{ eV} \quad (7)$$

Result: $H_0^{\text{T0}} \approx 66.2 \text{ km/s/Mpc}$ (−1.9% deviation from Planck). The exponent 41/4 requires physical justification from ξ -field theory.

For the complete numerical derivation, the step-by-step unit conversion (natural units $\rightarrow$ SI $\rightarrow$ km/s/Mpc), comparison with experimental measurements, and the resolution of the Hubble tension, see **Document 026** (Geometric Cosmology, Sections 4–6).

.5 Dimensional Analysis

Verification of dimensional consistency in natural units:

Quantity	T0 Expression	Dimension	Status
Geometric constant	$\xi = 4/3 \times 10^{-4}$	[1]	✓
Energy scale	$E_\xi = 1/\xi$	[E]	✓
Energy loss rate	$dE/dx = -\xi \cdot E$	[E ²]	✓
Redshift	$z = \xi \cdot x$	[1]	✓
Hubble parameter	$H_0 = E_H/\hbar$	[T ⁻¹]	✓

(Note of 1 Oct. 2026: The check marks in the rows energy loss rate and redshift do not survive scrutiny: $-\xi \cdot E$ has dimension [E], not [E²], and $\xi \cdot x$ has dimension [E⁻¹] (length), not [1]. Both rows only become consistent with an additional inverse length (e.g. H_0/c); see the note in the section on the energy loss mechanism.)

.6 Theoretical Advantages

The reinterpretation of the Hubble constant as an energy loss rate solves several problems:

1. **Elimination of dark energy:** The apparent cosmic acceleration arises naturally from distance-dependent energy loss. No exotic energy form with negative pressure is required.
2. **Fine-tuning problems solved:** The horizon problem vanishes since all regions have been in causal contact over infinite time. The flatness problem disappears for lack of initial conditions.
3. **Parameter reduction:** Where Λ CDM requires six independent parameters, T0 derives all cosmological observables from the single geometric constant ξ .

.7 Conclusion

$$H_0^{\text{T0}} = E_H/\hbar \approx 66.2 \text{ km/s/Mpc}, \quad E_H = E_0 \cdot \xi^{41/4} \quad (8)$$

The universe is not expanding. The Hubble constant measures energy loss in the ξ -field, not recession. The detailed derivation via finite element simulation of the T0 vacuum, frequency independence as geometric proof, and the resolution of the Hubble tension are found in Document 026.
