

Where does electrical energy actually flow?

Not in the wire, but in the field around it. Starting from the Goubau line “energy transport along a single wire without a return conductor” this book takes the Poynting vector $\mathbf{S} = \mathbf{E} \times \mathbf{H}$ seriously as the primary description and follows one principle across all scales: *the geometry of the carrier determines which couplings are allowed*.

Antenna engineering, atomic selection rules, Bragg conditions in crystals and the orbital resonances of the planets turn out to be the same structure on different carriers: coupling happens only where mode structures are compatible “regardless of field strength.

Within the Fundamental Fractal Geometric Field Theory (FFGFT) this is not an analogy but a consequence of the time“mass duality $\mathbf{T} \mathbf{f} \mathbf{A} \cdot \mathbf{m} = 1$ on the compact carrier $\mathbf{T} \mathbf{a}^{\text{top}} / \mathbf{a}, \mathbf{p}, \mathbf{f}$. In natural units, current is mass, voltage is energy and power is $\mathbf{E} \cdot \mathbf{m}$ “exactly, not approximately.

Every statement carries an epistemic marker “proven, numerically confirmed, structurally plausible, posited “and the book states clearly what it does not explain.
